Abstract—Extracting precise numerical data from visual graphs is a common challenge. This paper evaluates the accuracy of Multimodal Large Language Models (MLLMs), specifically Gemini 2.5 Pro, GPT 4.1 (Base and mini), and LLaMa 4, in reading exact values from a line graph at one-minute intervals. A baseline dataset and smoothed curve were generated using WebPlotDigitizer and spline smoothing. MLLM performance was assessed by comparing their visually extracted points against the baseline curve and quantifying the error using Mean Squared Error (MSE). While visual alignment varied, the results provide insights into the current capabilities and limitations of MLLMs for quantitative graph analysis tasks.

Index Terms—Visual Graph Analysis, Data Extraction, Multi-modal Large Language Models, WebPlotDigitizer.

I. Introduction

Visual graphs are essential for representing data trends, but extracting the underlying numerical data from static images can be difficult. Manual estimation is error-prone, and specialized tools like WebPlotDigitizer [1] require user interaction. The emergence of Multimodal Large Language Models (MLLMs) capable of processing visual information offers potential for automating this task.

This study investigates the accuracy of four current MLLMs - Gemini 2.5 Pro, GPT 4.1, GPT 4.1-mini and LLaMa 4 - for quantitative data extraction from a specific line graph, shown in Fig.1. The models were tasked with identifying the y-value of a target line at regular one-minute intervals along the x-axis. A high-resolution dataset was first extracted from the source graph image using WebPlotDigitizer. This dataset was then processed using smoothing splines to generate a canonical baseline curve and derive reference values at the target intervals.

The performance of each MLLM was evaluated both visually, by plotting their extracted points against the baseline curve (see Section III), and numerically, by calculating the Mean Squared Error (MSE) between their reported values and the baseline values. Grok was initially included but could not participate due to input processing issues. This analysis aims to quantify the precision of current MLLMs for this task and discuss their suitability for extracting exact numerical data from visual graphs.

The paper proceeds as follows: Section II describes the baseline generation and MLLM querying procedures. Section III presents the baseline data table, the visual comparison graphs, and the MSE results. Section IV offers a discussion of these results. Section V provides concluding remarks.

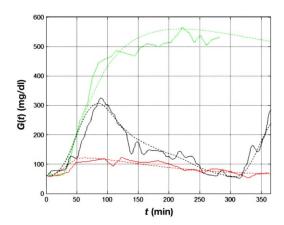

Fig. 1: The source line graph image used for data extraction by MLLMs and WebPlotDigitizer.

II. METHODOLOGY

The analysis compares MLLM-extracted data points against a baseline derived from meticulous digitization and smoothing.

A. Source Graph and Initial Extraction

The source image for this analysis is the 2D line graph shown in Fig.1, featuring a red line plotted against time (x-axis, 't [min]', approx. 0-350 min) and a measured quantity (y-axis, 'G(t) [mg/dl]'). The goal was to extract the y-value of the dotted red line at each interval of 1 minute, and plot those values.

WebPlotDigitizer (WPD) version 5 was employed to digitize the dotted red line from the source image, yielding a set of raw (x, y) coordinates after axis calibration, automatic extraction, and manual outlier removal. A truncated example of the raw data is:

```
3.390249058694458, 59.33243935793098 ... 362.9665066538365, 68.4993162415858
```

(The full raw dataset consists of 114 extracted points). See Appendix for full list of estimated points at 1 minute intervals from the extracted points.

B. Baseline Curve Generation and Data Derivation

To create a smooth, representative baseline from the potentially noisy WPD points, a cubic smoothing spline (k = 3)

was fitted using 'scipy.interpolate.make_splrep'. This method balances fidelity to the data points with overall curve smoothness by minimizing $\sum w_i * (g(x_i) - y_i))^2$, where g(x) is the estimation output at a given x (weighted least squares) [2]. The smoothing factor s was left to scipy for automatic evaluation.

The resulting smoothed curve represents the canonical baseline trend. This smoothed spline function was evaluated at the target 1-minute intervals to obtain the precise baseline y-values used for numerical comparison, listed in Table I. The visual representation of the baseline curve derived from the raw points is shown in the top-left panel of Fig.2.

TABLE I: Smoothed Baseline Y-Values at Select Intervals

X-Value (minutes)	Baseline Y-Value
0	55.2353
60	121.1254
120	110.5229
180	94.5300
240	81.6698
300	72.4751

C. Multimodal LLM Data Extraction

Four MLLMs were tested: Gemini 2.5 Pro, GPT 4.1 (Base and mini), and LLaMa 4. Each model received the original source graph image (Fig.1) and was prompted to provide the y-value of the dotted red line at each 1 minute interval. Each LLM was given one shot and supplied with the prompt: "The provided graph has 6 lines, and measures glucose levels over time [G(t)]. The only line we are interested in is the 'dotted red line'. Reply with a markdown format of an estimation of points on the dotted red line in 1 minute intervals. Your response should include one X, Y on each line. You should attempt to get results with y values accurate to e-4." Additions to the prompt were added when necessary to get the correctly formatted output. For access to Gemini 2.5 Pro (3-25) Google's AiStudio was used [3]. For access to LLaMa 4 Maverick [4] and GPT-4.1 (Base [5] and mini [6]) OpenRouter chat was used (Note: Grok 3 & 2 were also attempted but refused to admit they had access to the graph. Further testing through Grok.com or X.ai might show results).

D. Accuracy Assessment

MLLM accuracy was assessed numerically using the Mean Squared Error (MSE) between the MLLM-reported y-values $(y_{baseline})$ from Table I at the corresponding x-intervals:

$$MSE = \frac{1}{N} \sum_{i=1}^{N} (y_{mllm,i} - y_{baseline,i})^2$$
 (1)

where N is the number of points for which both the baseline and the MLLM provided a value.

III. RESULTS

This section presents the visual comparisons and the quantitative error summary.

A. Visual Comparison of MLLM Extractions

Figure 2 displays the comparison plots in a grid. The topleft panel shows the baseline smoothed curve derived from the raw WPD points. The subsequent panels overlay the points extracted by each MLLM onto this baseline curve, facilitating a direct visual assessment of their alignment.

B. Quantitative Accuracy Summary

The calculated Mean Squared Error (MSE), based on comparing MLLM-reported y-values to the baseline values in Table I, is summarized in Table II. Lower MSE values indicate better quantitative agreement with the baseline. Equation (1) was used for this calculation.

TABLE II: Mean Squared Error (MSE) for MLLM Data Extraction

MLLM Model	Mean Squared Error (MSE)
Gemini 2.5 Pro	31.38
LLaMa 4	108.46
GPT 4.1	315.88
GPT 4.1-mini	596.06

IV. COMPARISON AND DISCUSSION

For each MLLM tested, follow up calibration questions were asked to ensure the image was properly available. These included the colors and types of all the lines of the graph to ensure visual accessibility. All models tested passed, providing correct information regarding the visual details of the graph. From the results (Figure 2), it can be seen that the WPD extracted graph quite closely resembles the original graph. making it an accurate extraction of the dotted red line for the glucose levels. With it as a baseline, interesting patterns appear between the MLLMs evaluated. The first appearing pattern is that each MLLM struggled most on the noisiest areas of the graph, which in this case represents the beginning of the graph. Every MLLM tested had a result that overestimated the Y value of the start of the graph. In this test GPT-4.1-mini came the closest to the correct starting value, but underestimated the following bump and remaining values.

Of the four MLLMs tested, only three of them appeared to correctly estimate the overall shape of the glucose graph curve. These were Gemini 2.5 Pro, LLaMa 4, and GPT-4.1-mini. GPT-4.1 base was the only MLLM in this test which failed to identify the curvature in one shot, incorrectly indicating a positive slope on the trailing arc of the curve.

Quantitatively, Gemini 2.5 Pro gave the best performance. Excluding the first arc of the curve, the coordinates produced find themselves consistently placed in close proximity with the same curvature as the baseline graph (WPD), providing a MSE of only 31.38. Given Google's multimodal first approach to creating their models [7], it is unsurprising that it features a top ranking.

The remaining models, especially the GPT models, all struggled greatly, showing a critical lack of understanding for the given images.

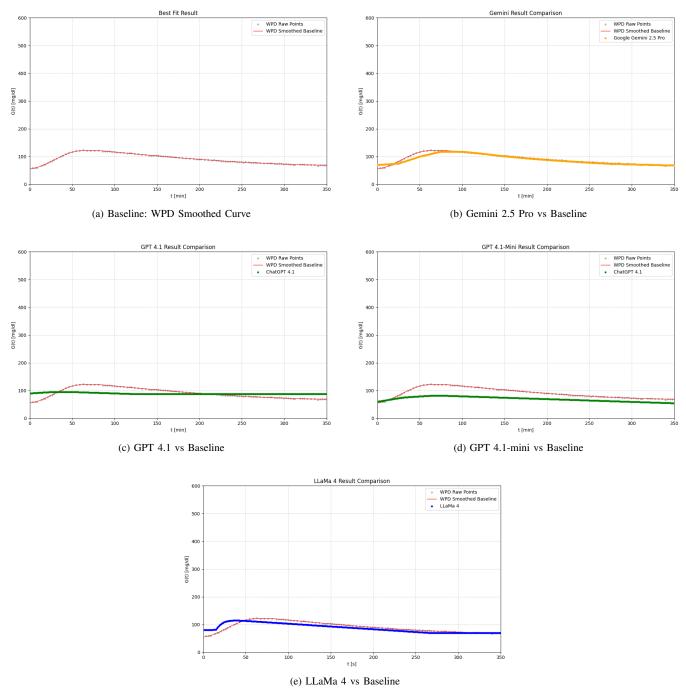

Fig. 2: Visual comparison of MLLM extracted points against the WPD smoothed baseline curve. (a) The baseline curve derived from WPD data. (b)-(e) Points extracted by Gemini, GPT, and LLaMa (markers) overlaid on the baseline (red line).

V. CONCLUSION

This study evaluated the capability of four state of the art Multimodal Large Language Models (MLLMs) - Gemini 2.5 Pro, GPT 4.1 Base, GPT 4.1-mini, and LLaMa 4 - to extract precise numerical data from a specific visual line graph at one-minute intervals. Performance was assessed against a baseline derived from WebPlotDigitizer and smoothing spline techniques, using both visual comparison (Fig.2) and quantitative Mean Squared Error (MSE) analysis (Table II).

The findings indicate significant variability in MLLM accuracy for this task. Google's Gemini 2.5 Pro demonstrated the strongest performance, achieving the lowest MSE (31.38) and providing visually aligned points that captured the overall curve shape reasonably well, particularly after the initial noisy segment. LLaMa 4 also replicated the general curve shape but with considerably higher error (MSE 108.46) and sharper value changes. The GPT models tested, especially GPT 4.1 Base (MSE 315.88), struggled significantly, with GPT 4.1 Base failing to correctly interpret the curve's overall trend in this single-shot test. While GPT 4.1-mini (MSE 596.06) captured the shape somewhat better than its base counterpart, its numerical accuracy was the lowest among the tested models. Notably, all models exhibited difficulty accurately estimating values in the initial, potentially noisier, section of the graph.

While MLLMs offer a potentially automated and user-friendly approach to graph data extraction, this analysis highlights that their current ability to deliver highly precise numerical data (such as the requested e-4 accuracy) directly from complex visual graphs remains limited and model-dependent. Gemini 2.5 Pro shows promise, aligning with its multimodal design focus, but even its output deviates from the baseline. For applications requiring high fidelity, methods combining specialized digitization tools like WebPlotDigitizer with appropriate data processing currently offer more reliable results. Future work should explore the performance of these and newer MLLMs across a wider variety of graph types and complexities, investigate the impact of different prompting strategies, and assess robustness to variations in image quality and style.
